

Redbanded Thrips, *Selenothrips rubrocinctus* (Giard) (Insects: Thysanoptera: Thripidae)¹

H. A. Denmark and D. O. Wolfenbarger²

The Featured Creatures collection provides in-depth profiles of insects, nematodes, arachnids and other organisms relevant to Florida. These profiles are intended for the use of interested laypersons with some knowledge of biology as well as academic audiences.

Introduction

The redbanded thrips, *Selenothrips rubrocinctus* (Giard), was first described from Guadeloupe, West Indies, where it was causing considerable damage to cacao. As a result, it was referred to as the cacao or cocoa thrips. The earliest report relating to this thrips was a report by W.E. Broadway in 1898, when he called attention to the “blight” of cacao.

Synonymy

Heliiothrips rubrocinctus Giard

Physopus rubrocinctus Giard (1901)

Heliiothrips (Selenothrips) decolor Karny

Heliiothrips (Selenothrips) mendex Schmutz

Brachyurothrips indicus Bagnall

(from [Forestry Compendium](#))

Distribution

The redbanded thrips is a tropical-subtropical species thought to have originated in northern South America (Chin and Brown 2008) and is found in the following areas:

- Asia—China, Malaya, Philippine Islands, Taiwan;
- Africa—Bioko, Ghana, Ivory Coast, Nigeria, Principe Island, Sierra Leone, Tanzania, Uganda, Zaire;
- Australasia and Pacific Islands—Hawaiian Islands, Mariana Islands, New Caledonia, New Guinea, Papua, and Solomon Islands;
- North America—United States (Florida), Mexico;
- Central America—Costa Rica, Honduras, Panama;
- West Indies;
- South America—Brazil, Ecuador, Guiana Peru, Suriname, and Venezuela.

In Florida, this species is found from Key West to Macclenny (Baker County in north Florida), but more generally it is found from the Orlando area south.

Description and Life Cycle

The female is about 1.2 mm in length and has a dark brown to black body underlain by red pigment chiefly in the first three abdominal segments; the anal segments retain

The nymph and pupa are light yellow to orange with the first three and last segments of the abdomen bright red. After hatching, there are two nymphal stages lasting nine to ten days. Fully-grown second stage nymphs are about 1 mm long. The two nymphal stages are followed by two resting stages (pre-pupal and pupal stages). The resting stages last three to five days before adults emerge (Chin and Brown 2008).

Eggs are inserted into the lower leaf surface and covered with a drop of fluid, which dries to form a black, disc-like cover (Astridge and Fay 2005). Females lay up to 50 eggs and live for up to one month. The eggs hatch within four days (Chin and Brown 2008). In Florida, the life cycle is completed in about three weeks, and there are several generations a year.

Hosts

The redbanded thrips is a pest of many plants. The locality and its flora usually determine the more prevalent hosts. In the West Indies, it has been a serious pest of cacao and mango. The species of tropical fruit trees, ornamentals and shade trees that it attacks are too numerous to list here. The favorite tropical fruit hosts in Florida are mango and avocado. It has also a problem in sweetgum trees in central Florida.

Economic Importance

The larvae and adults feed on the foliage and the fruit by piercing the epidermis with their mouthparts. Redbanded thrips prefer young foliage and their feeding causes distortion and drop. The thrips destroys the cells on which it feeds, causes injury to the fruit, and leaves unsightly dark colored droplets or blotches of excrement on the leaf surface. A more serious injury is leaf drop, which may

denude trees. Honeydew excretory products from redbanded thrips and other insect infestations fall to leaves, fruits or objects beneath, giving rise to the objectionable, fruit-degrading black sooty mold.

Management

Redbanded thrips are preyed upon by a large assortment of natural predators such as spiders, mites, lacewings, predatory thrips, and predatory bugs, especially minute pirate bugs (Chin and Brown 2008, Funderburk et al. 2000).

Chemical controls are not always necessary for this thrips, as natural controls are apparently effective most of the time. However, if chemical control is required, consult the *Vegetable Production Handbook of Florida*.
